Hydrology

Il Lago dell'Accesa è una depressione carsica caratterizzata dalla presenza di sorgenti al di sotto della superficie lacustre. Secondo alcuni studiosi, vi sarebbero connessioni idrauliche tra il Lago dell'Accesa e la sorgente dell'Aronna. (Rif Bibl n° 278)

Geology

Il bacino del sito è caratterizzato dalla presenza di diverse litologie appartenenti sia alla Serie Toscana che a quella Ligure. Le rocce più antiche sono del Carnico, appartengono alla formazione del Verrucano e si trovano nella parte orientale. Nei settori occidentali è presente il Calcere cavernoso del Retico, che costituisce i rilievi del Poggio Lecceta e di case Infernuccio e, nel punto più vicino al lago, la collinetta alta 179 m posta a occidente dello specchio d'acqua. Al margine meridionale del bacino sono presenti i litotipi delle Argille Scagliose Ofiolitifere, appartenenti alla Serie Ligure, di età cretaceo-Eocenica, che costituiscono i rilievi di poggio Corbello e del Podere del Montino. Delle formazioni affioranti quella che si presta maggiormente allo sviluppo del fenomeno carsico è il Calcere Cavernoso. (Rif Bibl n° 278)

Population, landcover and impacts

I dati demografici sono stati ricavati dal censimento ISTAT 1991. Il bacino del sito ricade interamente nel Comune di Massa Marittima in provincia di Grosseto. Sono presenti soltanto piccoli nuclei e case sparse.

Uses

Impacts

(Rif Bibl n° 374)

- Carico turistico elevato nella stagione estiva, soprattutto in relazione al suo utilizzo come luogo di balneazione
- Intensa attività venatoria
- Possibilità di incendi estivi

3. Description

Area (Ha) 52,00

Description

Profondo Lago di origine carsica, originatisi per crollo di una cavità ipogea. Si trova in una conca circondata da colline coltivate e boschi di latifoglie e rimboschimenti. Sono presenti fragmiteti, cenosi erbacee di sponda e prati umidi.

2nd character (permanency scale): 1- never flooded; 2- exceptionally flooded; 3- regularly flooded; 4- permanently flooded.

Hydrology remarks

Vi sono sorgenti all'interno del Lago dell'Accesa con punti di risorgenza sul fondale (tra i 13.1 e i 16.1 m di profondità) che fanno ritenere possibile l'esistenza di un sistema idrologico ipogeo ben sviluppato (278). L'emissario è il torrente Bruna.

Geology/ Geomorphology

IL Lago costituisce una dolina di origine carsica, originatasi a seguito dell'azione erosiva esercitata sul terreno circostante dalle sorgenti delle Venelle, dell'Arone, dell'Accesa. Tale azione, effettuata su rocce calcaree ha provocato lo sprofondamento del terreno e il deposito dell'acqua (K.C. n° 8). Osservazioni condotte in occasione di un'immersione nel settore di Sud-Ovest del lago hanno rivelato la presenza di un conglomerato costituito prevalentemente da clasti di Calcare Cavernoso e, in misura minore, da scisti, posto al disotto della coltre di sedimento che copre il fondale lacustre. La parte topograficamente più bassa del bacino idrografico è occupata da sedimenti quaternari e recenti, di origine gravitativa, alluvionale e lacustre. (278)
